## ***X-Ray Server As A Resource For Studies Using Grazing Incidence X-Ray Techniques***

## What is X-ray Server?

---

X-ray Server is a public project that I launched in **1997** with the goals to provide scientific community with a wider access to personal research results, establish scientific collaborations, and refine X-ray scattering models and scientific software.

The Server provides Web-based access to a number of programs implementing author's models in the field of X-ray diffraction and scattering. Thus, the project is a combination of physics and programming with physics being a lead and software being a tool.

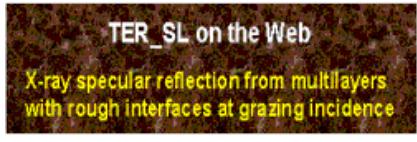

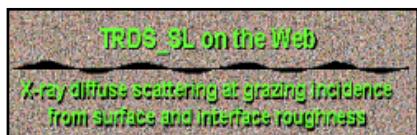

The software operates directly on the Server available for use without downloading. At present seven programs are accessible that have been used more than **120,000** times by more than **5,500** colleagues worldwide.

Currently at: <http://sergey.gmca.aps.anl.gov>

Formerly at: <http://sergey.bio.aps.anl.gov>

# Software available through X-ray Server

This site has been online since 1997 and has served **122,102** x-ray jobs

 <b>Xoh</b> on the Web !!!	<p><b>Xoh</b> interpolates dielectric susceptibilities <math>x_o</math> and <math>x_h</math> for some crystals and other materials in wide range of x-ray wavelengths with the option to compare data from different databases.</p> <p><b>Xoh-search</b> is a tool to search for Bragg planes under various conditions.</p>	<b>58,245</b> jobs

Based on ~17 research papers

**X0h** calculates material susceptibilities  $\chi_0$  and  $\chi_h$  for x-ray wavelength range by interpolating data tabulated in the International Tables for X-ray Crystallography and several other tables.

The highlight of **X0h** is the way it interpolates the dispersion corrections  $df'$  and  $df''$  [1]. The dispersion corrections are calculated with the formulae given by Don Cromer [Acta Crystallogr. vol.18 (1965) p.17-23]:

$$df' = \sum_{k=1}^{N_s} g_k P(X_k, N_k)$$

$$df'' = 0.5\pi \sum_{k=1}^{N_s} g_k (N_k - 1) / X_k^{N_k - 1}$$

First, **X0h** applies the above equations to known tabulated dispersion corrections and evaluates oscillator strengths  $g_k$ . Then, it uses calculated  $g_k$  to find the dispersion corrections of interest.

Once the  $\chi_0$  and  $\chi_h$  are found, **X0h** can fulfill a lot of useful service tasks like evaluating the HWFM of Bragg peaks, searching for Bragg reflections that satisfy certain conditions, and etc.

Originally developed for the studies of parametric X-ray radiation by relativistic electrons, now **X0h** is primarily used for synchrotron radiation and automatically called by all other server programs.

[1] O.M.Lugovskaya & S.A.Stepanov, (1991) Sov. Phys. Crystallogr. **36**, 478-471.

### X-rays:

- Wavelength (Å):
- Energy (keV):
- Characteristic line: Cu-Kα1

### Target:

- Crystal: Silicon
- Other material:
- Chemical formula:  and density (g/cm<sup>3</sup>):

### Reflection:

Miller indices:  1  1

### Database Options for dispersion corrections df1 , df2:

- Use XOh data (5-25 keV or 0.5-2.5 Å) -- recommended for Bragg diffraction.
- Use Henke data (0.01-30 keV or 0.4-1200 Å) -- recommended for soft x-rays.
- Use Brennan-Cowan data (0.03-700 keV or 0.02-400 Å)
- Compare results for all of the above sources.

## Background algorithm

**GID\_si** (Grazing Incidence Diffraction from Superlattices) was originally developed for GID (Fig.1a) from multilayers, but then extended to arbitrary Bragg case including coplanar (Fig.1b) and non coplanar asymmetric diffraction (Fig.1c).

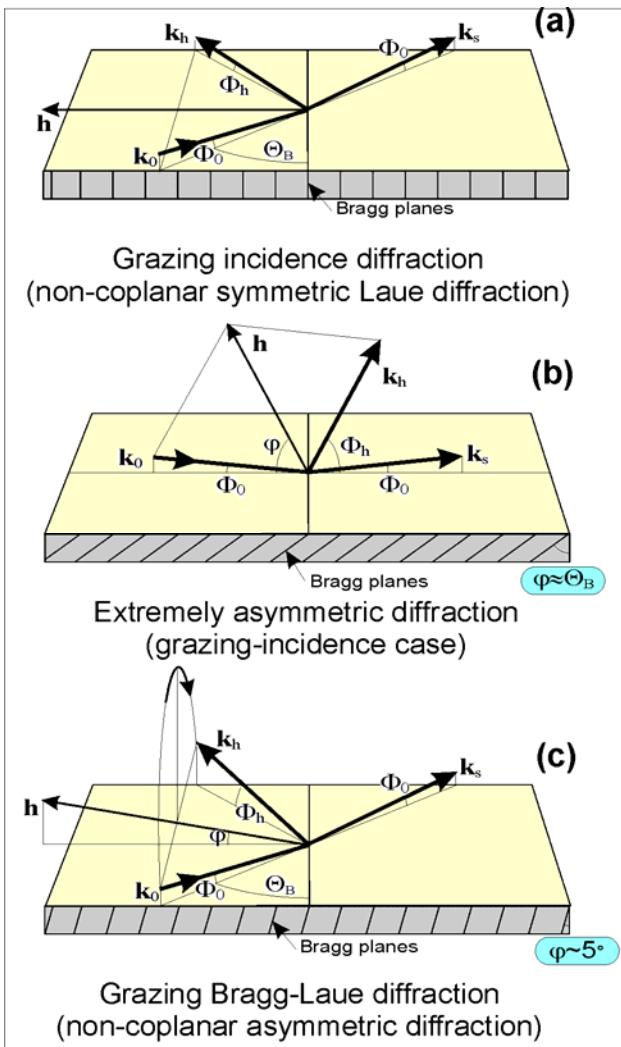

The program can calculate Bragg diffraction from imperfect crystals with given profiles of normal lattice strains  $da(z)/a$ , dielectric susceptibilities  $\chi_0(z)$ ,  $\chi_h(z)$ , and interface roughness height  $\sigma(z)$ .

The advantage of **GID\_si** over most of other Bragg diffraction simulation software is that it takes into account specular reflection and refraction of X-rays at crystal surface and interfaces in multilayers.

Replaces Takagi-Taupin equations for Grazing Incidence Diffraction!

## Background model

**TER\_sl** (Total External Reflection) software simulates X-ray specular reflection from multilayers with the account for interface roughness or transition layers using the same recursion algorithm as in **GID\_sl**.

The advantage of **TER\_sl** over the well know **Parratt** recursive technique is a faster convergence of recursions because **TER\_sl** expresses the reflection from a stack of N layers through the reflectivity of (N-1) layers, while the Parratt technique expresses the reflectivity of N-th layer via that of the underlying (N-1)-th layer.

By-product of **GID\_sl**:  
same recursion algorithm !

## Background algorithm

The **MAG\_sl** program solves the problem of resonant X-ray reflectivity from magnetic multilayers. The major application of X-ray resonant magnetic scattering is to probe thin magnetic films and magnetic multilayers. This is a hot topic related to studying magnetic heads for computer hard drives. However, since in this case the media susceptibility is a tensor, the conventional Parratt technique for calculating X-ray specular reflection is not applicable. The problem is solved in **MAG\_sl** applying a recursive algorithm for (2x2) scattering matrices similar to that of **GID\_sl**.

S.Stepanov and S.Sinha, Phys. Rev. B, **61** (2000) 15302-15311.

D.R.Lee, S.K.Sinha, D.Haskel, Y.Chi, J.C.Lang, S.A.Stepanov, and G.Srajer, Phys. Rev. B, **68** (2003) 224409-224427.

**MAG\_sl example:** difference between reflectivity of circular-plus and circular-minus polarized X-rays at E=849eV from 47Å capped Ni film.

## Background algorithm - I

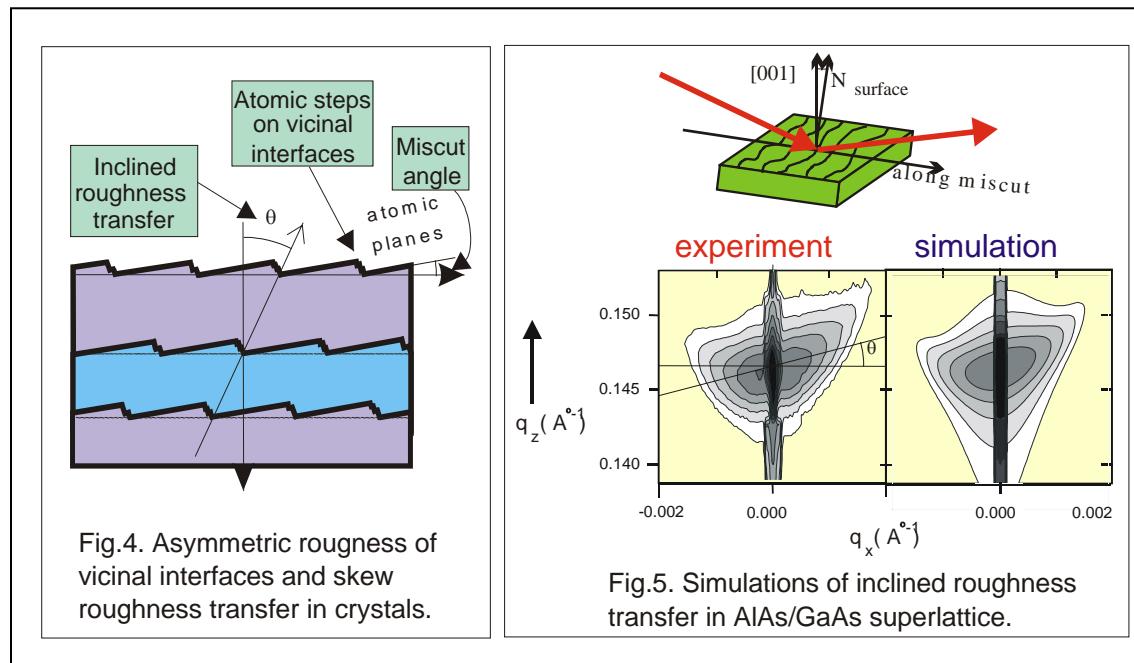

**TRDS\_SI** (Total Reflection Diffuse Scattering from Superlattices) was developed for the simulations of X-ray diffuse scattering from interface roughness in multilayers (Fig.1). This program implement a number of different models for interface roughness and for correlations between roughness at different interfaces in multilayers (Fig.2). Notable is the implementation of the model allowing to study wavelength-dependent inheritance of roughness in layer-by-layer grown multilayers (Fig.3).

V.M.Kaganer, S.A.Stepanov & R.Koehler, (1995) Phys. Rev. B **52**, 16369-16372.

## Background algorithm - II

Other notable models implemented in **TRDS\_sl** are the X-ray scattering from atomic steps on vicinal interfaces and the scattering due to inclined roughness transfer in crystalline multilayers (Fig.4). Both of those effects provide asymmetry of x-ray diffuse scattering (Fig.5), but each of different kind.

## Background algorithm

Kossel lines in case of  
multiple Bragg diffraction

**BRL** (Bragg/Laue) calculates multiple Bragg diffraction patterns with the algorithm based on the extended dynamical diffraction theory.

Typically the calculations of multiple Bragg diffraction are reduced to the eigenvalue problem for a  **$2N \times 2N$**  scattering matrix. However, when the diffraction geometry involves grazing X-ray waves, the calculations are reduced to the eigenvalue problem for  **$4N \times 4N$**  scattering matrix [Colella, Acta Cryst. **A30** (1974) 413].

**BRL** implements an algorithm where the calculations are reduced to a *generalized* eigenvalue problem for  **$2(N+N_s) \times 2(N+N_s)$**  scattering matrix where  $N_s$  is the number of grazing waves. Thus, if there are no grazing waves, the matrix size is  $2N \times 2N$  and if all of the waves are grazing it becomes  $4N \times 4N$ . In some cases the calculations are reduced dramatically.

S.Stepanov and A.Ulyanenkov, Acta Cryst. **A50** (1994) 579-585.

## BRL on the Web

X-ray multiple Bragg/Laue diffraction

## Web form

### Target:

Min. Intensity filter:  
 $(|xh/x_0|*100\% > \dots)$

### X-rays:

Wavelength (Å):

Energy (keV):

Characteristic line: Cu-K $\alpha$ 1

Fixed by coplanar case

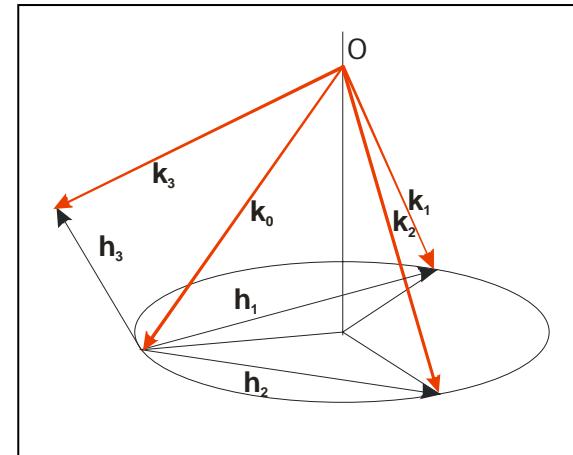

Fixed by Reflex-3:

### Database Options for dispersion corrections df1, df2:

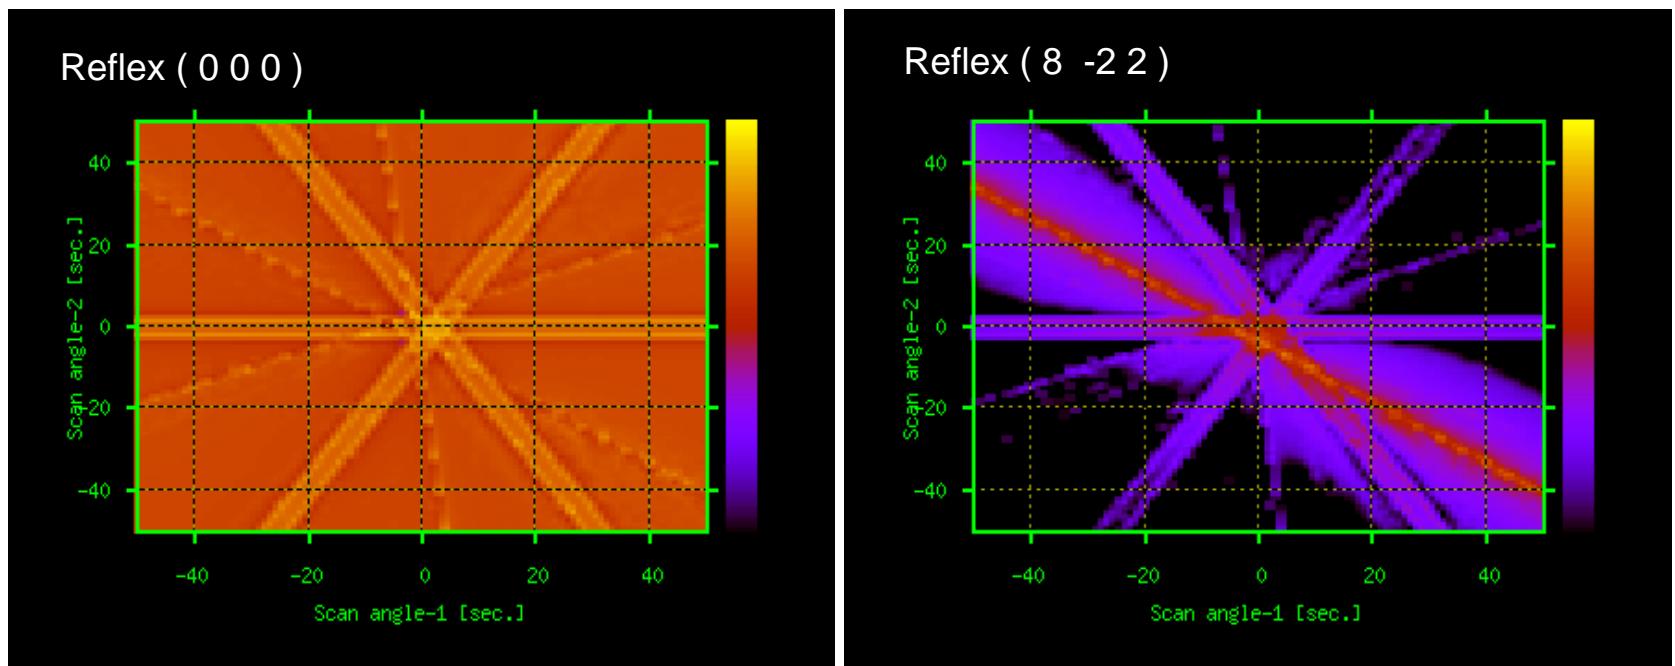

- Use X0h data (5-25 keV or 0.5-2.5 Å) -- *recommended*
- Use Henke data (0.01-30 keV or 0.4-1200 Å)
- Use Brennan-Cowan data (0.03-700 keV or 0.02-400 Å)

This is a Step-1 input form where one defines diffraction geometry. It calls an auxiliary program that looks for multiple diffraction combinations and generates Step-2 form.

At Step-2 user can enter scan parameters and include additional reflections if they were found and then call **BRL** to perform the multiple diffraction calculations.

```

Example script provided on the server to request & save  $\chi_{0r}$  and  $\chi_{0h}$  as a function of X-ray energy

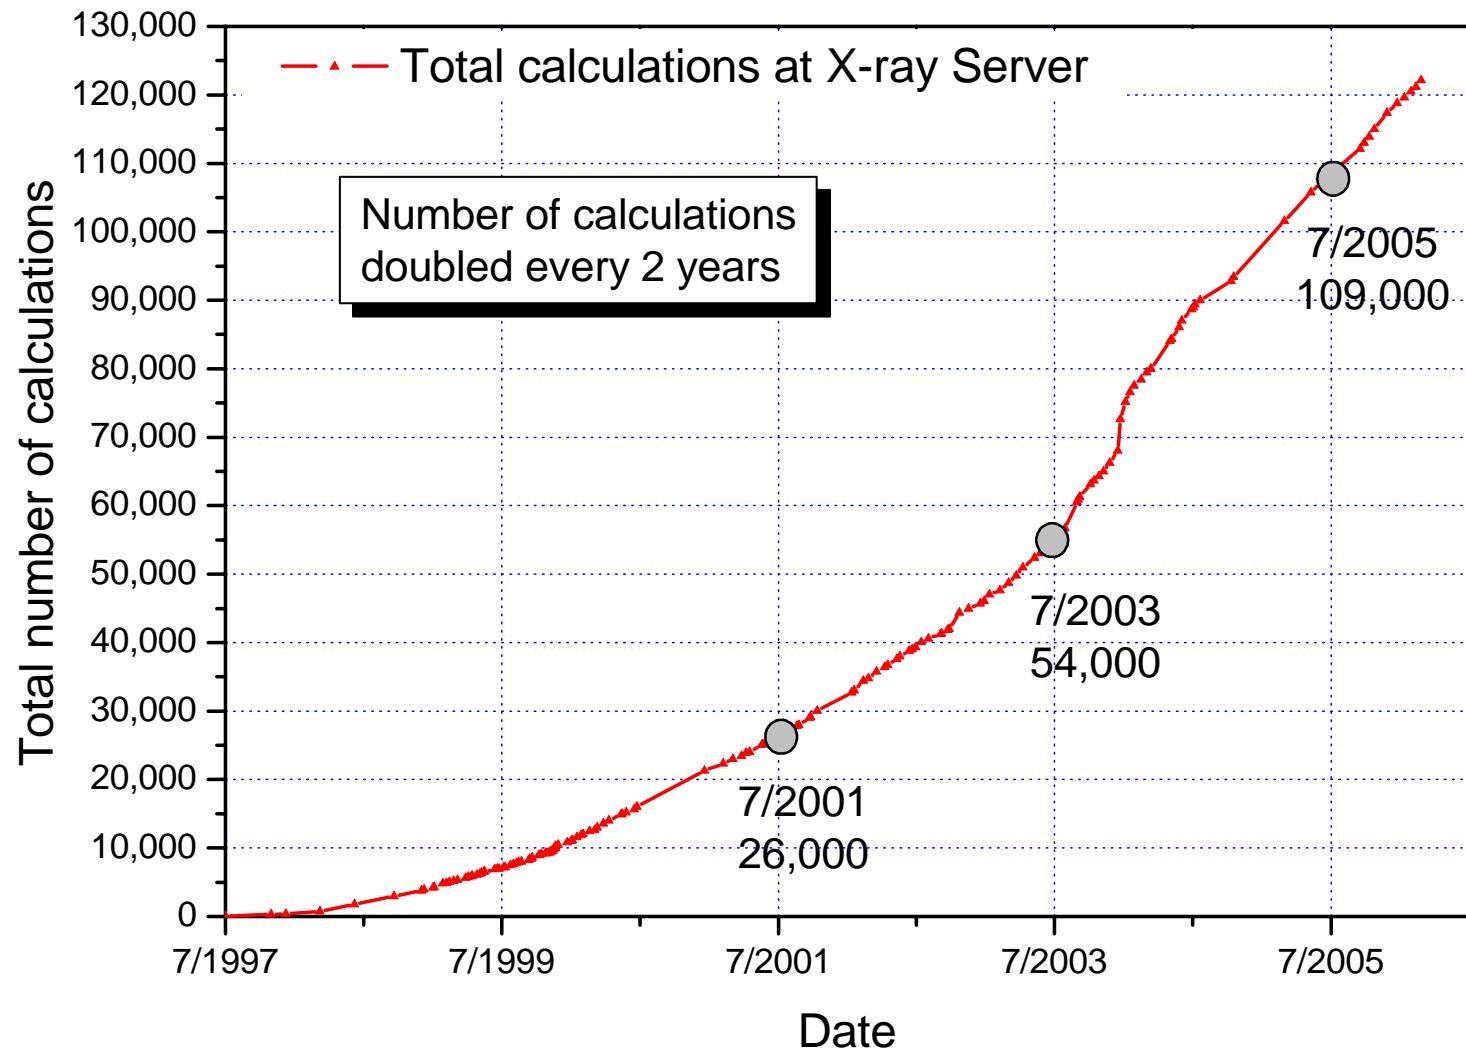

#Energy	xr0	xi0
10,	-0.18163E-04	0.35103E-06
11,	-0.13836E-04	0.24208E-06
12,	-0.12809E-04	0.14516E-05

Perhaps a more productive idea than online fitting is to provide tools to grab data by a fitting procedure running at a remote computer:

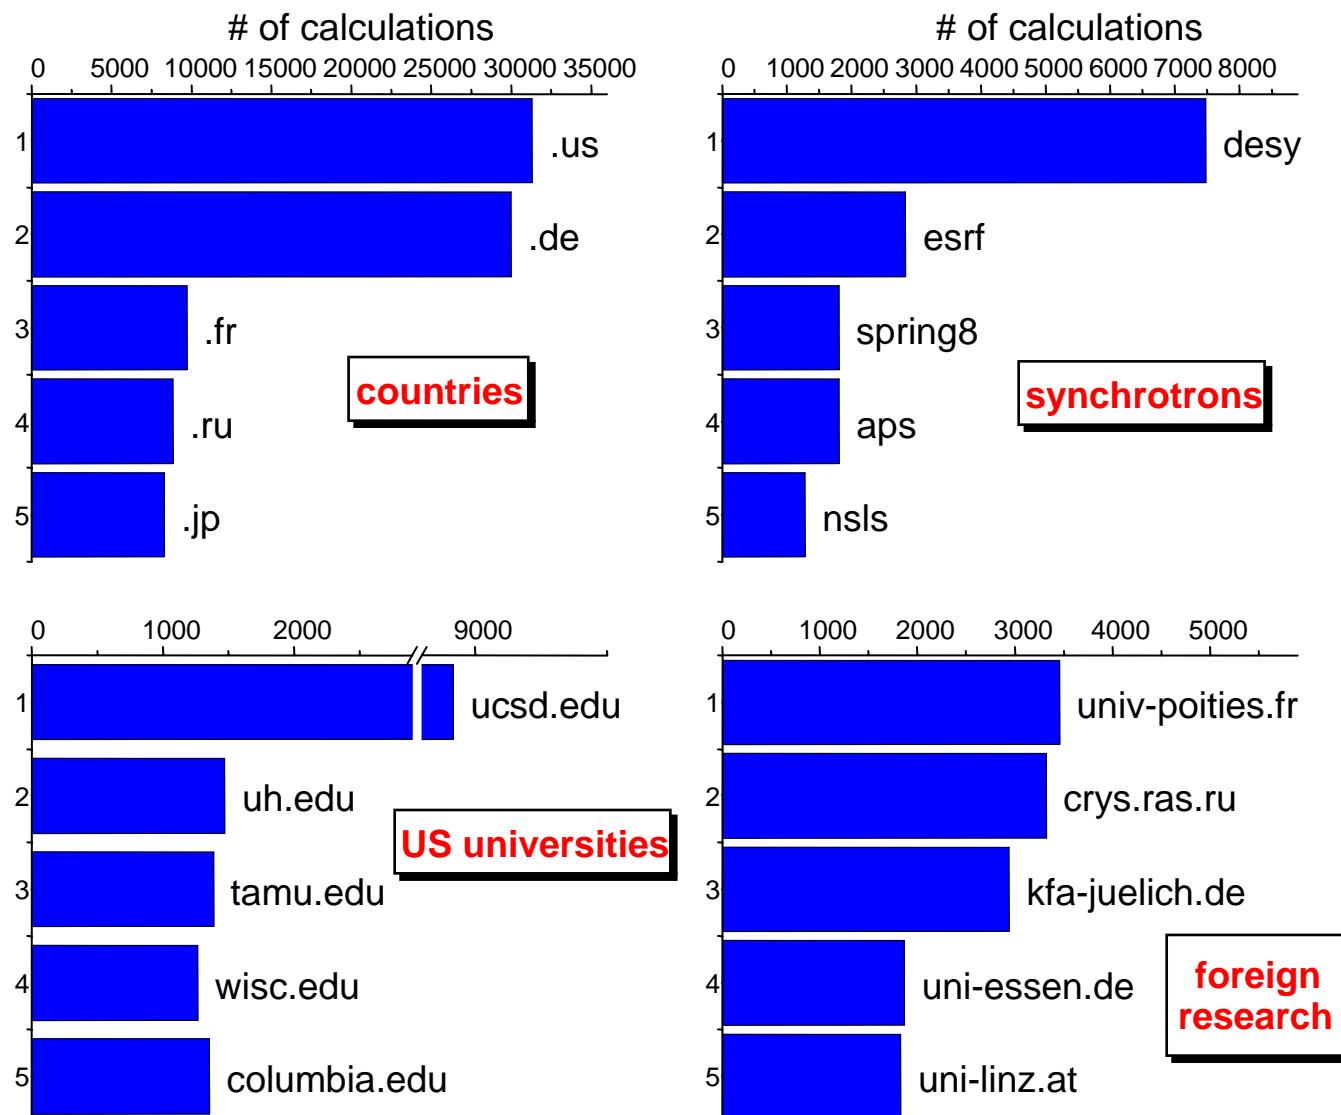

## Some X-ray Server statistics
